3.3 OPERATION

The function of engine transmits a power to torque converter through flexible plate.

The torque converter consists of an impeller wheel connected to the input side, a turbine connected to the output side and a stator wheel.

The power delivered from engine rotates the impeller wheel of the torque converter module, an impeller blade generates a fluid energy through being full of fluid in torque converter, this energy gives torque to turbine wheel.

Flow of the fluid flowing through rotating turbine wheel is changed by stator, this course causes opposite torque at stator and it is added to the turbine.

As the result of this, the output torque brings torque increase within the compass of oil capability.

When the truck starts running or goes to the uphill, a torque converter transmits a torque increased against engine torque to power transmission system of the transport.

When the truck runs at regular speed without increase speed, high torque is not required and output torque is gradually reduced.

Since the engine and transmission are connected through the fluid, some vibrations and shocks from the drive side is absorbed, safety of the transmission is secured.

Whether or not the truck travels, the engine continuously operates and torque is converted automatically according to load.

This system makes the drive operation much easier and work can be performed much more efficiently.

Output power of the torque converter is transmitted to the input shaft, forward clutch or a reverse clutch works according to gear choice of a driver.

The clutch power chosen at this time is connected to the output gear through the clutch gear.
