

3. MP-BGP is responsible for the exchange of VPN routes between the PE routers. PE1 advertises the VPNv4 route to PE2 using MP-BGP and Next-Hop itself. VPN-specific information is carried in MP-BGP attributes (VPNv4 prefix, VPN label, RT).
4. VRF vpn_a at PE2 imports the route, since the local import RT matches the RT in the route. The IPv4 route is inserted in its routing table, with PE1 as next hop. The VPN Label (L_u) is also recorded.
5. VRF vpn_a at PE2 advertises the IPv4 route to router CE2A using an IGP (RIPv2). This completes the distribution of the route to 172.16.1.0/24. (Site 1 of VPN A).

Figure 3. End-to-end route propagation.

Observe that the VPN routes are processed only by the PE routers. The other routers in the SP network need not know anything about VPN addresses and routes. In particular, the IGP running within the SP network is not involved in VPN route propagation (it supports the VPN only by providing internal routes needed to set up LSPs between PE routers). We use RIPv2 in the SP network.

Figure 4. Control plane: Route and label propagation.

Data plane operation

Figure 5 shows the packet forwarding for VPN A, from Site 1 to Site 2, after the final configuration of the MPLS-based VPNs. The MPLS packets carry a label stack consisting of two labels:

- The top label (L₁, L₂) corresponds to the LSP between PE1 and PE2 set up automatically by LDP.
- The bottom label (L_u) is the VPN label assigned to the VPN by the egress router (in this example, the label assigned to VPN A by PE2). This label allows the egress router to demultiplex the packet flow received on the LSP, identifying the packets belonging to each VPN.

Figure 5 shows that P1 pops the top label, instead of PE1. This procedure is called penultimate hop popping (PHP), i.e., an LSP label is removed by the penultimate router, rather than the last router, and was requested by PE1 during label distribution (implicit-Null label). This avoids an unnecessary label lookup at PE1, and it is the default behavior of Cisco routers.
