Towards embodied artificial cognition: TIME is on my side Michail Maniadakis, Marc Wittmann, Sylvie Droit-Volet, Yoonsuck Choe, 2015-06-05 From the moment of birth humans and animals are immersed in time all experiences and actions evolve in time and are dynamically structured The perception of time is thus a capacity indispensable for the control of perception cognition and action The last 10 years have witnessed a remarkable resurgence of interest in timing and time perception with a continuously increasing number of researchers exploring these innate abilities However existing robotic systems largely neglect the key role of time in cognition and action This is a major barrier for accomplishing the long term goal of symbiotic human robot interaction The critical question is how is time instantiated in a biological system and how can it be implemented in an artificial system Recent years have for example seen an increasing focus on the relationship between affective states and the experience of time The influence of affective states on subjective time seems to depend on the embodiment of emotions intertwined affective and interoceptive states may create our subjective experience of time Since robotic systems are in essence embodied information processing systems that interact with the real world we hope to inspire a reciprocal exchange of ideas between the field of Robotics and the Cognitive Neurosciences In this research topic we call researchers from different disciplines Robotics Neurosciences and Psychology to present their empirical work their models or reviews on the question of how time judgments are instantiated in biological and artificial systems Of particular interest are papers on time perception in humans and animals with a focused interest on embodied time perception i.e. the influence of affective and body states on time judgments Moreover the present Research Topic seeks to gather papers discussing the key role of time on different aspects of robotic cognition as well as modeling approaches We are interested in paving the way for a new generation of intelligent computational systems that incorporate the sense of time in their processing loop and thus accomplish more efficient and more advanced cognitive capacities

What can simple brains teach us about how vision works Davide Zoccolan, David D. Cox, Andrea Benucci, R. Clay Reid, 2015-11-18 Vision is the process of extracting behaviorally relevant information from patterns of light that fall on retina as the eyes sample the outside world Traditionally nonhuman primates macaque monkeys in particular have been

viewed by many as the animal model of choice for investigating the neuronal substrates of visual processing not only because their visual systems closely mirror our own but also because it is often assumed that simpler brains lack advanced visual processing machinery. However, this narrow view of visual neuroscience ignores the fact that vision is widely distributed throughout the animal kingdom, enabling a wide repertoire of complex behaviors in species from insects to birds, fish, and mammals. Recent years have seen a resurgence of interest in alternative animal models for vision research, especially rodents. This resurgence is partly due to the availability of increasingly powerful experimental approaches, e.g., optogenetics and two-photon imaging, that are challenging to apply to their full potential in primates. Meanwhile, even more phylogenetically distant species such as birds, fish, and insects have long been workhorse animal models for gaining insight into the core computations underlying visual processing. In many cases, these animal models are valuable precisely because their visual systems are simpler than the primate visual system. Simpler systems are often easier to understand, and studying a diversity of neuronal systems that achieve similar functions can focus attention on those computational principles that are universal and essential. This Research Topic provides a survey of the state of the art in the use of animal models of visual functions that are alternative to macaques. It includes original research methods articles, reviews, and opinions that exploit a variety of animal models, including rodents, birds, fishes, and insects, as well as small New World monkey, the marmoset, to investigate visual function. The experimental approaches covered by these studies range from psychophysics and electrophysiology to histology and genetics, testifying to the richness and depth of visual neuroscience in non-macaque species.
