Dementia diagnostics in primary care Anna Segernäs Kvitting, 2019-09-20

Background Age is the greatest risk factor for developing dementia and the total number of people aged 60 years and above is expected to more than double globally from 2013 to 2050 1 Primary health care PHC is important for basic diagnostic evaluations Objective test measurements have been shown to be more reliable than a patient's subjective memory complaints in dementia assessments 2 However several studies indicate the low use of objective cognitive screening tools in dementia diagnostics in PHC 3 Some general practitioners GPs do not perceive today's cognitive instruments as helpful in the diagnostic process and administration problems have been reported in PHC 4 5 The overall aim of this thesis was to investigate the accuracy of several cognitive tests used in dementia assessments in PHC especially among older patients A Quick Test of Cognitive Speed AQT Cognistat and Cognitive Assessment Battery CAB The normative values of the Mini Mental Status Examination MMSE in the oldest old was also studied Methods The studies included in this thesis are from two different study populations Studies I II and IV Patients with and without cognitive symptoms were recruited from four primary health care centres in Sweden between 2007 and 2009 Study III The Elderly in Linköping Screening Assessment ELSA 85 cohort population examined people born in 1922 in the municipality of Linköping Sweden Results Study I Results showed that AQT is a usable test for dementia diagnosis in PHC Sensitivity for AQT is superior to the Clock Drawing Test CDT equivalent to MMSE and the combination MMSE and CDT The AUC for AQT was 0.773 valued good enough Study II Overall the results for Cognistat in this study are superior to MMSE and CDT also in combination Cognistat is promising for improved dementia diagnosis in PHC with a quick and easily administered multi domain test for dementia assessments Study III This study presents valuable information about normative MMSE data for the oldest patients Results suggest using the 25th percentile in MMSE of 25 to 26 points and indicate that MMSE 26 is as a reasonable cut off for cognitive decline and further medical evaluation in older persons aged from 85 to 93 years Study IV In summary the additive value of the CAB test in dementia investigations in PHC is not obvious In addition to questionable accuracy the test is quite time consuming and normative values are scarce By introducing the numerical sum CABsum the accuracy was increased Conclusion In conclusion objective cognitive tests are an important part of dementia diagnosis in PHC and there is a need for improved instruments and norm values From our results several cognitive quick tests are usable in PHC MMSE AQT and Cognistat but they have some disadvantages MMSE 26 is a reasonable cut off for cognitive decline in the oldest patients 85 to 93 years from a well educated population with quite good socioeconomic There is a great interest in finding short and better multi domain instruments but the additive value of CAB in dementia investigations in PHC is questionable
